Methods 3: Multilevel Statistical Modeling and Machine Learning

Week 02: *Multilevel linear regression* September 10, 2024

The course plan

Week 1: Introduction

Instructor sessions: Setting up R and Python and recollection of the general linear model

Week 2: Multilevel linear regression

Instructor sessions: Modelling subject level effects – and how do they differ from group level effects?

Week 3: Link functions and fitting generalised linear multilevel models Instructor sessions: What to do when the response variable is not continuous?

Week 4: Evaluating Generalised linear mixed models

Instructor sessions: How do we assess how models compare to one another?

Week 5: Explanation and Prediction
Instructor sessions: Code review

Week 6: Mid-way evaluation and Machine Learning Intro

Instructor sessions: Getting Python Running

Week 7: Linear regression revisited (machine learning)

Instructor sessions: How to constrain our models to make them more predictive

Week 8: Logistic regression revisited (machine learning)

Instructor sessions: Categorizing responses based on informed guesses

Week 9: Dimensionality Reduction, Principled Component Analysis (PCA)

Instructor sessions: What to do with very rich data?

Week 10: Outlook, unsupervised classification and neural networks

Instructor sessions: Data with no labels and networks

Week 11: Organising and preprocessing messy data

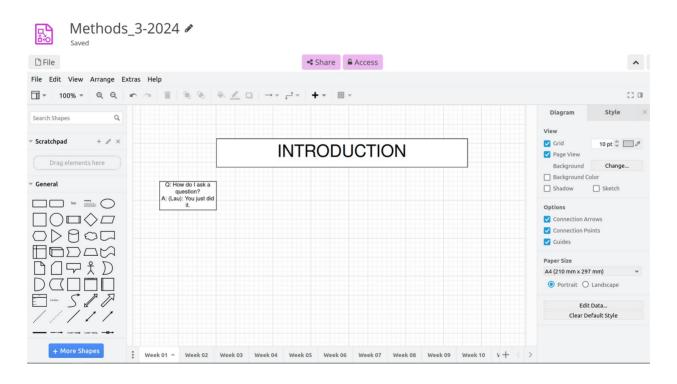

Instructor sessions: Code review

Week 12: Final evaluation and wrap-up of course

Instructor sessions: Ask anything!

Troubleshooting

CONDA ENVIRONMENTS

Learning goals and outline

Multilevel linear regression

- 1) Understanding the motivations for doing multilevel modelling
 - Using all the data
 - Respecting the data distribution
- 2) Understanding the basics of multilevel modelling
 - Different kinds of design matrices, *X* and *Z*
 - Variance-covariance matrices
 - Pooling: complete pooling, no pooling and partial pooling

Overall motivation

We want to use all the information in the data while respecting the data distributions the data is generated from

The four classical levels of variables

Nominal

- examples: true/false, correct/incorrect, female/male, dog/cat, apples/pear, also called *categorical*
- they are *names* of categories, but it does not make sense to order them

Ordinal

- examples: senior/junior, adult/child 1/2/3
- they are also *names* of categories, but there is an explicit or implicit *ordering*, i.e. one is greater than another

Interval

- examples: the year 1984 AD; the temperature 100 °C
- they are *continuous*, and there is *ordering*, e.g. 100 °C > 90 °C. And intervals can be compared, e.g. the interval from 80 °C to 100 °C is as long as the one from 40 °C to 60 °C
- crucially, there is no real 0; the year before 1 AD is not characterised by absence of time; and 0 °C is not characterised by the absence of temperature This means that we cannot say that, say, 40 °C is twice as high a temperature as 20 °C

Ratio

- examples: the temperature 273 K, the reaction time of a subject
- they are *continuous*, there is *ordering* and there is a *real 0*.
- Thus we can say that 200 K is twice the temperature of 100 K, as 0 K is the absence of temperature; and we can say that subject 2, 400 ms, is twice as fast as subject 1, 200 ms, because 0 ms is the time when the event happened

Sub-optimal practices

TREATING VARIABLES AS ANOTHER LEVEL THAN THEY ARE

sleepstudy (Ime4)

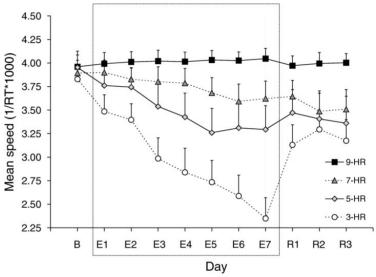

R Documentation

Reaction times in a sleep deprivation study

Description

The average reaction time per day (in milliseconds) for subjects in a sleep deprivation study.

Days 0-1 were adaptation and training (T1/T2), day 2 was baseline (B); sleep deprivation started after day 2.

Q: judging from the figure: what kind of predictor is *Day* modelled as? And should it have been modelled otherwise?

Sub-optimal practices AGGREGATION – part 1

Journal of Experimental Psychology: General

Q's:

- What do each of the grey dots represent?
- What kind of response data is present at the singletrial level?
 - And how is the response data categorised here?
- Within a single-subject level framework, what would be the appropriate model to fit?
- Can confidence intervals extend beyond proportion correct 1 or 0 with the approach used here?

Figure 3

Mean Proportions of Correct Responses for the Recognition Task in Experiments 1a (Familiarization Only) and 1b (Reproduction Only)

Note. Chance performance is at 0.5, shown by the horizontal line, and asterisks indicate performance differing significantly from chance. Error bars represent 95% confidence intervals around the mean.

Sub-optimal practices AGGREGATION – part 2

"The percentage of epochs that were excluded from data analysis (due to artifacts) for hits and correct rejections ranged from 28% to 42% in the four experimental conditions." section 2.4.2 "Three factorial ANOVA's were calculated for hits and correct rejections [...]. For these [electrode] sites, data were averaged separately for the left and right hemisphere but only for those 1 s intervals of an epoch which represent the first 1000 ms after presentation onset of the memory set and frame." section 2.4.5

Q: What may be a problem when data is aggregated like that?

General Linear Model

When all you have is a hammer, everything looks like a nail

Normally distributed variable (an interval or ratio variable)

$$\Sigma_{\theta} = \sigma^2 \Lambda_{\theta} \Lambda_{\theta}^{T} \tag{4}$$

Bates D, Mächler M, Bolker B, Walker S (2015) Fitting Linear Mixed-Effects Models Using Ime4. Journal of Statistical Software 67:1–48. https://doi.org/10.18637/jss.v067.i01

Subject.(Intercept) Subject.Days.(Intercept) 0.96674177 0.01516906

Subject.Days 0.23090995

Q: What would the plot look like if there was no covariance between predictors?

$$Corr = \frac{9.6}{\sqrt{(612.1 \times 35.07)}} = 0.07$$

CC BY Licence 4.0: Lau Møller Andersen 2024

20

Why do we care about covariance?

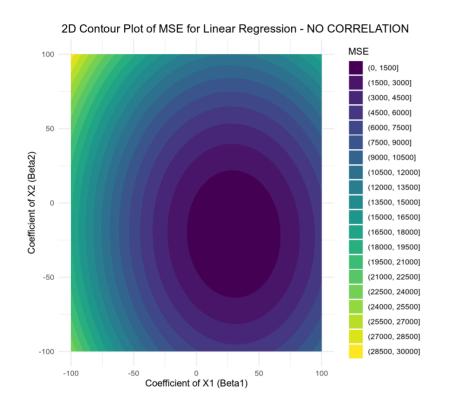

Too much covariance between predictors, and your model doesn't converge ...

... and even in you get convergence, the estimated coefficients may be sensitive to small changes in input

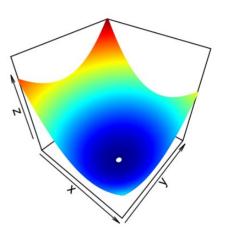

```
get.SIGMA <- function(model) sigma(model)^2 * (getME(model, 'Lambda') %*% getME(model, 'Lambdat'))
for(seed in c(1, 7))
{
    print(paste('Random seed is:', seed))
    set.seed(seed)
    sleepstudy$Days2 <- 2 * sleepstudy$Days + rnorm(length(sleepstudy$Days))
    model <- lmer(Reaction ~ Days + Days2 + (Days + Days2 | Subject), data=sleepstudy)
    print(paste('Estimated rank is:', rankMatrix(get.SIGMA(model))[1]))
    print('\n')
}</pre>
```

```
[1] "Random seed is: 1"
boundary (singular) fit: see help('isSingular')
[1] "Estimated rank is: 36"
[1] "\n"
[1] "Random seed is: 7"
Advarsel i checkConv(attr(opt, "derivs"), opt$par, ctrl = control$checkConv, :
    Model failed to converge with max|grad| = 0.0433554 (tol = 0.002, component 1)
[1] "Estimated rank is: 54"
[1] "\n"
```

True function: $y = 31x_1 - 21x_2$ $x_1 = rnorm(100)$; $x_2 = rnorm(100)$

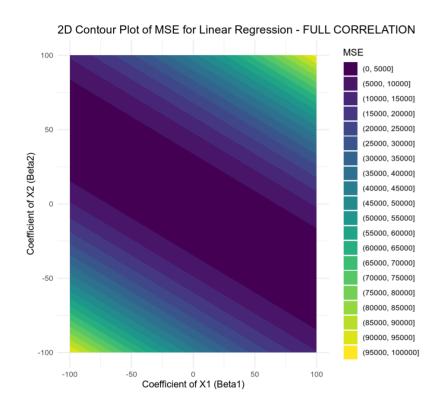

3D Contour Plot of MSE for Linear Regression - NO CORRELATION

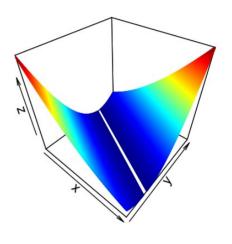

Full rank

True function: $y = 31x_1 - 21x_2$ $x_1 = rnorm(100)$; $x_2 = 2x_1$

3D Contour Plot of MSE for Linear Regression - FULL CORRELATION

Hint for the future

With "big data", the variancecovariance matrices will matter a lot (machine learning)

Pooling

Overview – pooling

Complete pooling

- Ignores the categorical predictor, e.g. Subject, altogether
- Im(Reaction ~ Days)

No pooling

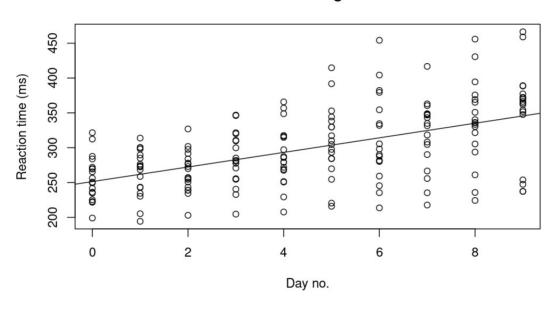

- Overfits the categorical predictor, e.g. *Subject*, i.e. overstates the variation among *Subjects*
- Im(Reaction ~ Days * Subject 1)

Partial pooling

- A compromise between the two extremes above. If a group, e.g. Subject, has few observations (high variance), it will be shrunk towards the overall mean. If Subject has many observations (low variance), it will be shrunk less towards the overall mean
- Imer(Reaction ~ Days + (Days | Subject)

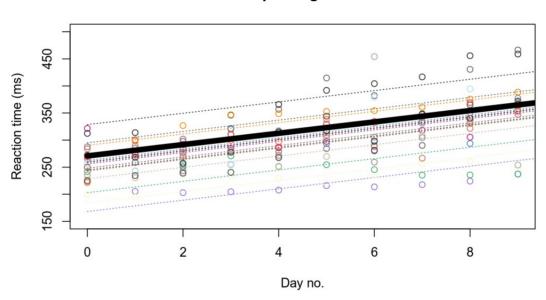

Complete pooling

Pooled linear regression

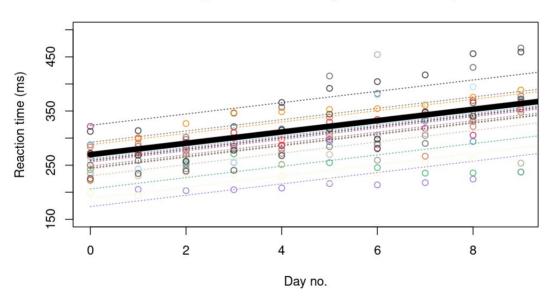

No pooling

No-pooling model

Partial pooling

Linear regression with subject-level intercepts

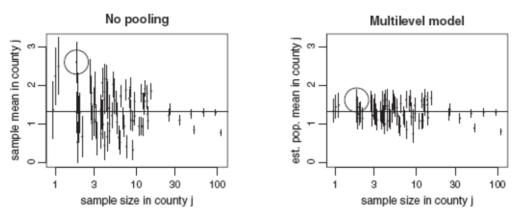

Figure 12.1 Estimates ± standard errors for the average log radon levels in Minnesota counties plotted versus the (jittered) number of observations in the county: (a) no-pooling analysis, (b) multilevel (partial pooling) analysis, in both cases with no house-level or county-level predictors. The counties with fewer measurements have more variable estimates and larger higher standard errors. The horizontal line in each plot represents an estimate of the average radon level across all counties. The left plot illustrates a problem with the no-pooling analysis: it systematically causes us to think that certain counties are more extreme, just because they have smaller sample sizes.

Gelman A, Hill J (2006) Data Analysis Using Regression and Multilevel/Hierarchical Models. Cambridge University Press

How is shrinking done?

HOW IS BIAS ADDED?

Penalised least squares:

$$r^{2}(\theta, \beta, u) = \rho^{2}(\theta, \beta, u) + ||u||^{2}$$
 (14)

 $\rho^{2}(\theta, \beta, u)$ is the (weighted) residual sum of squares

$$\mu_{Y|U=U} = X \beta + Z \Lambda_{\theta} U$$

(compare with: $\mu_Y = X \beta$ from classical regression)

Another way to look at shrinking

OR HOW TO ADD BIAS

$$\alpha_{j} = \frac{\frac{n_{j}}{\sigma_{y}^{2}}}{\frac{n_{j}}{\sigma_{y}^{2}} + \frac{1}{\sigma_{\alpha}^{2}}} (\bar{y}_{j} - \beta \bar{x}_{j}) + \frac{\frac{1}{\sigma_{\alpha}^{2}}}{\frac{n_{j}}{\sigma_{y}^{2}} + \frac{1}{\sigma_{\alpha}^{2}}} \mu_{\alpha} \quad (12.4)$$

$$\alpha_j$$
: partially pooled response $(\bar{y}_j - \beta \bar{x}_j)$: subject estimate of mean μ_α : group estimate of mean σ_y^2 : within-group variance σ_α^2 : between-group variance

$$\frac{\frac{n_j}{\sigma_y^2}}{\frac{n_j}{\sigma_y^2} + \frac{1}{\sigma_\alpha^2}} + \frac{\frac{1}{\sigma_\alpha^2}}{\frac{n_j}{\sigma_y^2} + \frac{1}{\sigma_\alpha^2}} = 1$$

$$\frac{\frac{n_j}{\sigma_y^2}}{\frac{n_j}{\sigma_y^2} + \frac{1}{\sigma_\alpha^2}}$$
: proportion assigned to subject estimate

: proportion assigned to group estimate

Q's:

What happens to the estimated α_i , when respectively n_{r} , σ_{y} , or σ_{α} :

- 1) increases?
- 2) decreases?

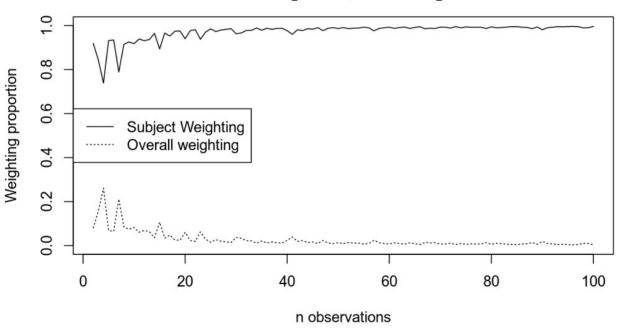

CC BY Licence 4.0: Lau Møller Andersen 2024

3) is 0? 4) goes towards infinity?

```

When $\sigma_{\alpha} > \sigma_{y}$ 100 SIMULATIONS

Proportions as dependent on n observations Between-sigma: 4, Within-sigma: 3

When $\sigma_{\alpha} < \sigma_{y}$ 100 SIMULATIONS

Proportions as dependent on n observations Between-sigma: 4, Within-sigma: 10

The course plan

Week 1: Introduction

Instructor sessions: Setting up R and Python and recollection of the general linear model

Week 2: Multilevel linear regression

Instructor sessions: Modelling subject level effects – and how do they differ from group level effects?

Week 3: Link functions and fitting generalised linear multilevel models Instructor sessions: What to do when the response variable is not continuous?

Week 4: Evaluating Generalised linear mixed models

Instructor sessions: How do we assess how models compare to one another?

Week 5: Explanation and Prediction

Instructor sessions: Code review

Week 6: Mid-way evaluation and Machine Learning Intro

Instructor sessions: Getting Python Running

Week 7: Linear regression revisited (machine learning)

Instructor sessions: How to constrain our models to make them more predictive

Week 8: Logistic regression revisited (machine learning)

Instructor sessions: Categorizing responses based on informed guesses

Week 9: Dimensionality Reduction, Principled Component Analysis (PCA)

Instructor sessions: What to do with very rich data?

Week 10: Outlook, unsupervised classification and neural networks

Instructor sessions: Data with no labels and networks

Week 11: Organising and preprocessing messy data

Instructor sessions: Code review

Week 12: Final evaluation and wrap-up of course

Instructor sessions: Ask anything!

Next time –

Link functions and fitting generalised linear multilevel models

- Generalising general models
- Link functions
 - transforming from one scale to another
 - inverse functions
- Maximum likelihood estimation

Reading questions

- Chapter 5, Gelman & Hill
 - Why do we want to transform $X_i\beta$ using $logit^1$?
 - What is an odds ratio?
 - How are logistic regression coefficients interpreted?
- Sections 6.1 and 6.2 Gelman & Hill
 - What is the parameter, θ , of the Poisson distribution?
 - Why may overdispersion be an issue?
